TITLE: Methods for encapsulating plasmids in lipid bilayers

Detailed Description Text (12):

Although directed to the transfer of nucleic acids, and in particular to the transfer of plasmids to cells, the particles of the present invention can be used for delivering essentially any polyanionic molecule. As noted in the Background of the Invention, typical lipid-nucleic acid formulations are formed by combining the nucleic acid with a preformed cationic liposome (see, U.S. Pat. Nos. 4,897,355, 5,264,618, 5,279,833 and 5,283,185. In such methods, the nucleic acid is attracted to the cationic surface charge of the liposome and the resulting complexes are thought to be of the "sandwich-type" depicted in FIG. 1. As a result, a portion of the nucleic acid or plasmid remains exposed in serum and can be degraded by enzymes such as DNase I. Others have attempted to incorporate the nucleic acid or plasmid into the interior of a liposome during formation. These methods typically result in the aggregation in solution of the cationic lipid-nucleic acid complexes (see FIG. 2). Passive loading of a plasmid into a preformed liposome has also not proven successful. Finally, the liposome-plasmid complexes which have been formed are typically 200 to 400 nm in size and are therefore cleared more rapidly from circulation than smaller sized complexes or particles. The present invention provides a method of preparing serum-stable plasmid-lipid particles in which the plasmid is encapsulated in a lipid-bilayer and is protected from degradation. is Additionally, the particles formed have a size of about 50 to about 150 nm, with a majority of the particles being about 65 to 85 nm. The particles can be formed by either a detergent dialysis method or by a modification of a reverse-phase method which utilizes organic solvents to provide a single phase during mixing of the components. Without intending to be bound by any particular mechanism of formation, FIG. 3 depicts a detergent dialysis approach to the formation of the plasmid-lipid particles. With reference to FIG. 3, a plasmid or other large nucleic acid is contacted with a detergent solution of cationic lipids to form a coated plasmid complex. These coated plasmids can aggregate and precipitate. However, the presence of a detergent reduces this aggregation and allows the coated plasmids to react with excess lipids (typically, non-cationic lipids) to form particles in which the plasmid is encapsulated in a lipid bilayer. As noted above, these particles differ from the more classical liposomes both in size (liposomes being typically 200-400 nm) in that there is little or no aqueous medium encapsulated by the particle's lipid bilayer. The methods described below for the formation of plasmid-lipid particles using organic solvents follow a similar scheme.

DOCUMENT-IDENTIFIER: US 6248353 B1

TITLE: Reconstitution of purified membrane proteins into preformed liposomes

Brief Summary Text (6):

There are essentially four presently known mechanisms for incorporating, i.e., reconstituting, proteins into liposomes. See Rigaud, J- L., et al., "Liposomes as Tools for the Reconstitution of Biological Systems," p. 71-88, in Liposomes as Tools in Basic Research and Industry, ed. Philippot, J. R. and Schuber, F., CRC Press, Boca Raton, Fla. (1995). One method involves the use of an organic solvent. However, such procedures often result in the denaturation of the proteins. A second method uses mechanical means to produce large and small unilamellar vesicles from MLVs by swelling of the dry phospholipid films in excess buffer. Such mechanical means include sonication of MLVs, forcing multilamellar lipid vesicles through a French press, or cycles of freeze-thawing or dehydration-rehydration. Drawbacks with sonication include variability and inactivation of certain proteins by sonication as well as production of small liposomes. A third process involves the direct incorporation of proteins into preformed small unilamellar liposomes, also termed spontaneous incorporation. Such methods are usually catalyzed by low cholate or lysolecithin concentrations. Problems with these methods include the wide size distribution of the proteoliposomes, heterogeneous distribution of the protein among the liposomes and presence of the non-phospholipid impurities, required for an effective protein incorporation, that would affect performance of those liposomes. The fourth and most often used method of incorporating proteins into liposomes involves the use of detergents. In such a method, the proteins and phospholipids are cosolubilized in a detergent to form micelles. The detergent is then removed, resulting in the spontaneous formation of bilayer vesicles with the protein incorporated therein. The detergent is incorporated into liposome as well as the protein and thus, these methods require removal of the detergent by methods such as dialysis, gel exclusion chromatography or adsorption on hydrophobic resins. The methods that use detergent are very slow because the detergent removal must be as complete as possible and also because a phase change that takes place during this process slows detergent removal even further. The detergent is also difficult to remove completely. Another disadvantage is that one cannot control the orientation of protein incorporated into the liposomes by using the detergent methods.

Brief Summary Text (21):

The present invention relates to methods for reconstituting purified membrane proteins into preformed liposomes, in the presence of at least one type of fatty acid. In one preferred embodiment, the present invention relates to such methods that do not use detergent.

Brief Summary Text (30):

The present invention relates to methods of reconstituting purified membrane proteins into preformed liposomes. The present methods enable such reconstitution without the use of detergent, as required in presently heretofore known methods. The term "detergent" refers to amphipathic compounds, for example long-chain hydrocarbon, terminated at one end by a polar group, often charged. These compounds include molecules whose charged polar group is highly soluble in water whereas the hydrocarbon does not readily enter the aqueous environment. Detergents, as used herein, include those without any charge, e.g., n-octyl-.beta.-D-glucopyranose (octylglucoside), anionic detergents, which carry a negative charge, e.g., dodecyl sulfate, and cationic detergents, which carry a positive charge, e.g.,

hexadecyltrimethylammoniumbromide.

Brief Summary Text (33):

The methods of the present invention enable the reconstitution of purified membrane proteins into preformed liposomes without the need to use detergent for the step of reconstitution.

TITLE: Compositions and methods useful for inhibiting cell death and for delivering an agent into a cell

Detailed Description Text (27):

Methods are known in the prior art for preparing immunoliposomes. Immunoliposomes are prepared, for example, by adsorption of proteins (e.g., immunoglobulin) on the liposomal surface; incorporation of native protein into the liposome membrane during its formation (e.g., by ultrasonication, detergent dialysis or reverse phase evaporation); covalent binding (direct or via a spacer group) of a protein to reactive compounds incorporated into the liposomes membrane; noncovalent hydrophobic binding of modified proteins during liposome formation or by the incubation with preformed liposomes; and indirect binding, including covalent binding of immunoglobulin protein via a polymer to the liposome (see Torchilin, V. P. CRC Critical reviews in Therapeutic Drug Carrier Systems, vol. 2(1), hereby incorporated by reference).

ATTY-AGENT-FIRM: Burns, Doane, Swecker & Mathis, LLP

ABSTRACT:

Methods and compositions are described for nonliposomal lipid complexes in association with toxic hydrophobic drugs such as the polyene antibiotic amphotericin B. Lipid compositions are preferably a combination of the phospholipids dimyristoylphosphatidylcholine (DMPC) and dimyristoylphosphatidylglycerol (DMPG) in about a 7:3 mole ratio. The lipid complexes contain a bioactive agent, and may be made by a number of procedures, at high drug:lipid ratios. These compositions of high drug:lipid complexes (HDLCS) may be administered to mammals such as humans for the treatment of infections, with substantially equivalent or greater efficacy and reduced drug toxicities as compared to the drugs in their free form. Also disclosed is a novel liposome-loading procedure, which may also be used in the formation of the HDLCS.

TITLE: Conjugate having a cleavable linkage for use in a liposome

Detailed Description Text (94):

Ethanol was removed from the liposome suspension by diafiltration. A histidine/sodium chloride solution was prepared by dissolving histidine (10 mM) and sodium chloride (150 mM) in sterile water. The pH of the solution was adjusted to approximately 7. The solution was filtered through a 0.22 μm Durapore filter. The liposome suspension was diluted in approximately a 1:1 (v/v) ratio with the histidine/sodium chloride solution and diafiltered through a polysulfone hollow-fiber ultrafilter. Eight volume exchanges were performed against the histidine/sodium chloride solution to remove the ethanol. The process fluid temperature was maintained at about 20-30.degree. C. Total diafiltration time was approximately 4.5 hours.

TITLE: Fusogenic liposomes that are free of active neuraminidase

Brief Summary Text (21):

A further method of preparing liposomes comprises the rapid injection of an ethanolic solution of lipid into aqueous saline or a buffer which has previously been purged with nitrogen. The resulting liposome preparation is then concentrated by ultrafiltration with rapid stirring under nitrogen at low pressure to avoid the formation of larger non-heterogeneous liposome. The ethanol may be removed from the vesicle fraction by analysis or washing with an ultra-filter. The polypeptide may be present in aqueous solution or alternatively the liposome fraction obtained after ultrafiltration may be lightly sonicated with the polypeptide.

TITLE: Liposomal compositions for enhanced retention of bioactive agents

Detailed Description Text (21):

DSPC/Chol (55:45; mol:mol), DSPC/Chol/G.sub.M1 (45:45:10; mol:mol:mol), DSPC/Chol/Stearylamine (45:45:10), DSPC/Chol/AL-1 (45:45:10), or DSPC/Chol/Sphingosine (45:45:10) were prepared by dissolving the lipid mixtures in 95% ethanol (1 mL/100 mg lipid). The mixtures were then heated at 60.degree. C. for 30 min. Subsequently, a preheated (60.degree. C.) solution of 300 mM citric acid (pH 4 or pH 2) was added (3 mL buffer/100 mg total lipid) while vigorously vortex mixing. The resulting multilamellar vesicles ("MLVs") were heated at 60.degree. C. for an additional 30 min., followed by extrusion ten times through two polycarbonate filters with 100 nm pores. The extrusion device, obtained from Lipex Biomembranes (Vancouver, British Columbia, Canada), was also maintained at 60.degree. C. Ethanol was removed from the liposome preparation by dialyzing (Spectra/Por 2 dialysis tubing, 12,000-14,000 molecular weight cut-off against two changes (200 mL dialysis buffer per 1 mL of sample) of 300 mM citric acid (pH 4 or 2) over a 24 h period. It has been determined that greater than 99.9% of the ethanol is removed using this procedure.

Nov 16, 1993

DOCUMENT-IDENTIFIER: US 5262168 A

TITLE: Prostaglandin-lipid formulations

Brief Summary Text (8):

Another technique used to form liposomes is the "reverse phase evaporation" (REV) process of Papahadjopoulos (U.S. Pat. No. 4,235,871, issued Nov. 25, 1980). Such process forms oligolamellar lipid vesicles wherein the aqueous material to be encapsulated is added to lipids in organic solvent, forming an water-in-oil type emulsion. The organic solvent is removed, forming a gel. The gel is dispersed in aqueous medium converting it to a suspension. Yet another technique is the detergent-dialysis process (Enoch et al., 1979, Proc. Natl. Acad. Sci., 76:145). In this process, lipid is mixed with a detergent such as deoxycholate in aqueous solution, sonicated, and the detergent removed by gel filtration. A further technique is the ethanol infusion technique of Batzri et al. (1973, Biochim. Biophys. Acta., 298:1015), for forming small unilamellar vesicles, whereby an ethanol solution of lipid is injected into the desired aqueous phase, forming liposomes of about 30 nm to about 2 um in diameter. The residual ethanol may then be removed by rotoevaporation.

File: USPT

Jun 21, 1988

DOCUMENT-IDENTIFIER: US 4752425 A

TITLE: High-encapsulation liposome processing method

Detailed Description Text (29):

The infusion process was continued to a final lipid concentration of about 300 .mu.mole/ml, at which about 75% of the drug was encapsulated in the liposomes formd. As in the Example III preparation, which also involved uncharged lipid components, the liposome sizes were heterodisperse, having sizes up to about 10 microns. The ethanol remaining in the liposome suspension after removal of the "Freon" solvent can be removed, if desired, by diafiltration, molecular sieve chromatography, or the like. However, the presence of the ethanol in the suspension does not appear to effect liposome stability or reduce encapsulation efficiency.
